1.1.4 Main challenges

1.1.5 Elastic gridshell : a definition

The invention of the gridshell concept is commonly attributed to Frei Otto, a German architect who devoted several years to gridshells. In 1975 he achieved the famous *Mannheim Multihalle* [31], a wooden shell of 7500 m², in collaboration with the engineer Edmund Happold (Arup). Literally, the word “gridshell” refers to grids behaving like shells : from a mechanical point of view that means stresses acting on the structure are mainly transmitted through compression and traction. These structures can cross large-span with very little material.

However, according to the historic evolution of the concept, characterizing a gridshell as the combination of a structural concept – a grid behaving like a shell – and a specific construction process – using the bending flexibility of the material – seems to be more accurate. The Mannheim project (in which a wooden regular and planar grid, lacking shear stiffness, is elastically deformed up to a targeted shape with the help of stays, and then braced and covered) is regarded as the starting point of this new concept.

The Mannheim project is regarded as the starting point of this new concept for which a wooden regular and planar grid, lacking shear stiffness, is elastically deformed up to a targeted shape with the help of stays, and then braced and covered. This type of gridshell,

Chapter 1. Elastic gridshells

known as elastic gridshell, offers a very elegant manner to materialize freeform shapes from an initially flat and regular grid, which obviously has many practical benefits: planar geometry, standard connection nodes, standard profiles and so on.

At present, the architectural significance of grid shells can hardly be fully envisioned. Too little experience has been gained as yet. However, the first signs of a grid shell architecture are already apparent. The projects planned and executed to date and the results of this research work indicate possibilities that open up a wide field of applications for grid shells. Two things stand out above all. The first is the nearly unlimited variety of forms that can be realized with grid shells, the second is the fact that there is no closed shell surface, but rather a simple, spatially curved grid composed of rods. Both features are of fundamental significance. They fully characterize the architectural essence of the grid shell support structure. [11, p. 250]

“From the inverted form to the gridshell” [11, p. 179]

1.2 Elastic gridshells : a thorough project review

No thorough historic review is available about executed projects of elastic gridshells although some partial reviews have been done time to time on the occasion of scientific works or construction projects. This review aims at filling this gap by giving an overview of the development of the concept from the very beginning to the very last experiments. Only known built projects have been identified and reported here. The only condition for a project to belong to this review is to comply with the definition of what an elastic gridshell is (see ??), independently to any other consideration (material, fabrication, size, cladding, ...).

The informations collected during this research work are given in table format in appendix (see ??). A synthetic presentation of these datas is proposed to the reader in fig. 1.1, where projects are ordered by date, span, covered area and material.

The books edited by the *Institut für leichte Flächentragwerke* are of great interest to understand the beginnings. *IL10 Grid Shells* [11] has a precise inventory of the first experiments from 1962 to 1976, while *IL13 Multihalle Mannheim* [10] focuses on the construction of the Multihalle in Mannheim. *Timber Gridshells: Architecture, structure and craft* [13] is a significant effort but focuses exclusively on medium to large scale projects in timber. A small but general partial review is also available in [14]. An interesting review is also given by Quinn and Gengnagel [59] as part of his research work on new erection methods. A review of bracing and cladding systems is done in [15]. A review of formfinding methods is done in [36]. Finally, various valuable reviews are available in the thesis by Douthe [20], Bouhaya [7], Tayeb [60], and Lafuente Hernández [40].

1.2.1 The beginnings : from the first prototype to the German Pavilion

Frei Otto started his studies in architecture in 1947 in Berlin, Germany, and completed his doctorate on tensile structures in 1953. This first work was published and translated later in the 60's. He then began to work in the field of lightweight structures using physical models such as soap films or hanging nets, and photographic measurements.^{1,2} These tools were essentials for his exploration of forms and structures as there were no computers at that time.

¹In the 19th and 20th centuries model testing was at the heart of structural innovation [1]. Analog models were employed successfully by well-known architects and engineers to go beyond the limits of existing knowledge (A. Gaudi, H. Isler, F. Candela, F. Otto, ...) and are still employed today where numeric models failed to represent accurately some physical phenomena (for instance in wind analysis for high rise towers and bridges).

²"Photography is the medium through which the form and content of a model are communicated. It is one of our most important tools in that it provides the basis for documentation and information, supplements our creative potential [...] " [11, p. 56]

(a) Knot detail

(b) Steel lattice

Figure 1.2 – Steel gridshell built in 1962 in Berkeley, USA.

Steel Gridshell, Berkeley, USA, 1962

Simultaneously, he became interested by the study of lightweight shells and the way they were form-found. One of his very first elastic gridshell was built in 1962 with students at Berkeley, USA [11, p. 270]. It is funny to remark that this first gridshell was not a timber gridshell but a steel gridshell made out of twin steel rods linked in a grid fashion by bolts with clamping plates (see fig. 1.2a). This first experiment demonstrated at small scale the ability to bend a regular grid with no shear rigidity into a curved shape (see fig. 1.2b). The grid was loosely braced and shell effects were not investigated.

Essen Gridshell, Essen, Germany, 1962

The same year he designed and built a first timber gridshell at Essen, Germany [11, p. 272]. The prototype – a single-layer gridshell spanning 17 m and covering an area of 198 m² – was made with 3-ply laminated timber profiles in hemlock pine (see fig. 1.3a). The cross-section of the profiles was rectangular (60 mm x 40 mm) and the elements were assembled in a grid fashion with simple steel bolts. Once erected, nothing was specifically done to improve the in-plane shear stiffness of the grid and activate a shell behavior. Finally, the structure was covered with a transparent plastic foil nailed directly on the grid's profiles (see fig. 1.3b).

German Pavilion Auditoria, Montreal, Canada, 1967

Fiver years later, on the occasion of the *1967 International and Universal Exposition* in Montreal, Canada, Frei Otto was appointed to design the German Pavilion : a large cable net tent prefiguring the realization of the olympic stadium of Munich, Germany, in 1972.³

³Actually, Frei Otto became the director of the newly founded *Institute for Lightweight Structures* (Institut für Leichte Flächentragwerke or IL) at the University of Stuttgart in 1964. It was the IL that was commissioned by the German government to conduct research in connection with the planning of the German pavilion for the exposition in Montreal.

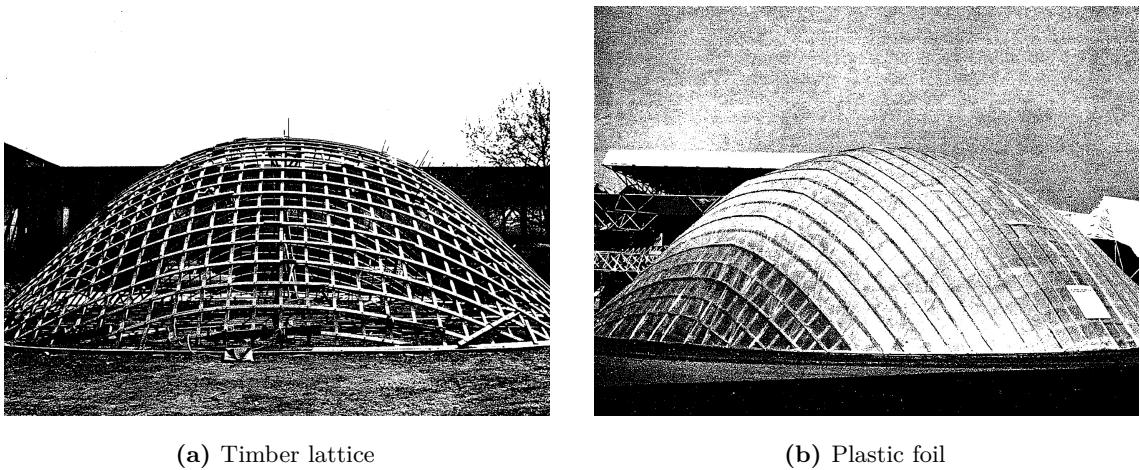

Figure 1.3 – Timber gridshell built in 1962 in Essen, Germany.

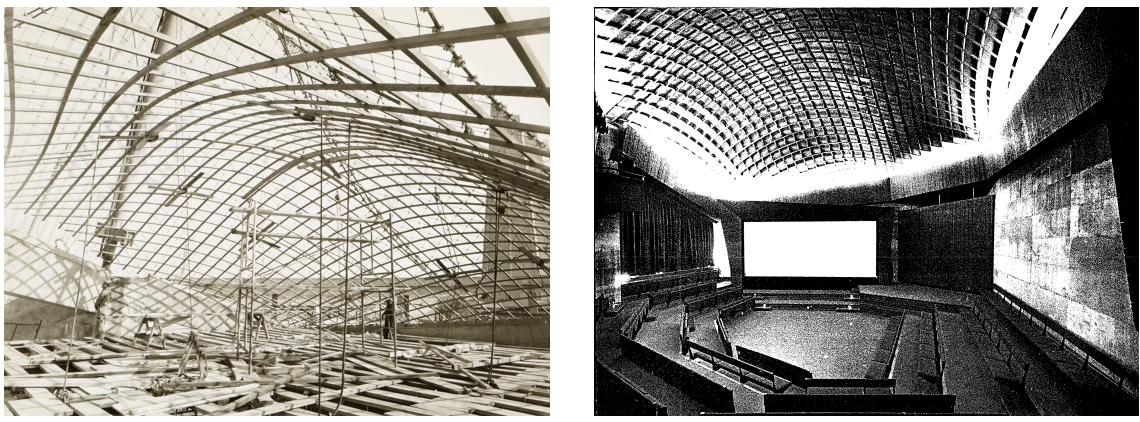

Figure 1.4 – Timber gridshell built in 1967 in Montreal, Canada.

The pavilion required two auditoria and these were designed using the principle of elastic gridshell [11, p. 274]. All together, the auditoria covered an area of 365 m^2 and spanned 17.5 m. The construction technique employed in Montreal was quite similar to the one developed in Essen, but this time the grid was fully braced with a layer of nailed plywood boards and offered a proper roofing made out of insulation panels covered with a PVC coated fabric (see [figures 1.4a](#) and [1.4b](#)).

The two gridshells built in Montreal mark a significant step in the maturation process of the technique leading to the major realization of Mannheim in 1976 : a methodology has emerged to progress “from the inverted form to the gridshell” [11, p. 179] ; main construction details have been validated ; various erection methods have been tested ; mid-scale buildings have been built to host public. However, due to the over complexity of these structures, lots of unknowns remained unsolved at this stage and the behavior of the

structures could not be fully predicted.⁴

It is worth to mention that several unexecuted large-scale projects were studied by Frei Otto between 1967 and 1973 at the *IL* or at the *Atelier Warmbronn*.⁵ These projects are basically documented in [11, pp. 278 - 288] and reveal that he was training his capacity to master large-scale projects with the technique of elastic gridshells for more conventional building projects (wave pool, swimming hall, multi-purpose hall, auditorium, . . .).

1.2.2 Mannheim Multihalle : the completion of a decade of research

The project of the Multihalle started in 1970, when the decision was made that Mannheim, Germany, would hold the Bundesgartenschau in 1975.⁶ The architects of the project, *Carl Mutschler & Partners*, consulted Frei Otto at *Atelier Warmbronn* as he was starting to get known in the field of innovative lightweight structures. This is how the idea of the gridshell was introduced in the project [44].

A thorough report on the project is available in [10]. A more condensed but still precise description of the engineering problematics related to this projects are availables in the excellent papers from Happold and Liddell [31] and Liddell [44].

Multihalle, Mannheim, Germany, 1975

Mannheim is an unprecedented realization because it is more than twenty times larger than the previously built gridshells in Montreal and is meant to last many years and not only for the duration of a short-term exhibition. The timber lattice, still existing in 2017, covers an area of 7400 m² (see fig. 1.5b). It is composed of two interconnected domes, one for the multi-purpose hall (span : 60 m | height : 20 m) and one for the restaurant (span : 50 m | height : 18 m).

Although the constructif system deployed at Mannheim clearly inherited from the previous developments, the challenge was such that it had to be revisited. In particular the main additions were the introduction of the double-layer system and the proper bracing of the grid. A major advance was also the use of the very first numeric models to study the structure.

The double-layer system was introduced to tackle two issues : the grid needed some flexibility to be bent into the desired shape, but once erected it should provide sufficient bending stiffness to resist disturbing loads and avoid a buckling collapse.⁷ One erected, the

⁴“Snow accumulations in the throat of the common edge beam probably caused one of the two grid shells of project Montreal to buckle in a relatively flat region. The diameter of the buckled area was about 3 meters. Neither grid rod was broken, i.e. the buckling progressed elastically. It might have been possible to press the buckled area back into shape.” [11, p. 219]

⁵Atelier Warmbronn is the architectural studio founded by Frei Otto in 1969.

⁶The Bundesgartenschau is a national horticultural exhibition that takes place every two years in Germany.

⁷Theoretically, self-weight loads would produce only compression in the members because the (funicular) form of the grid resulted from the inversion of a hanging chain model in pure tension.

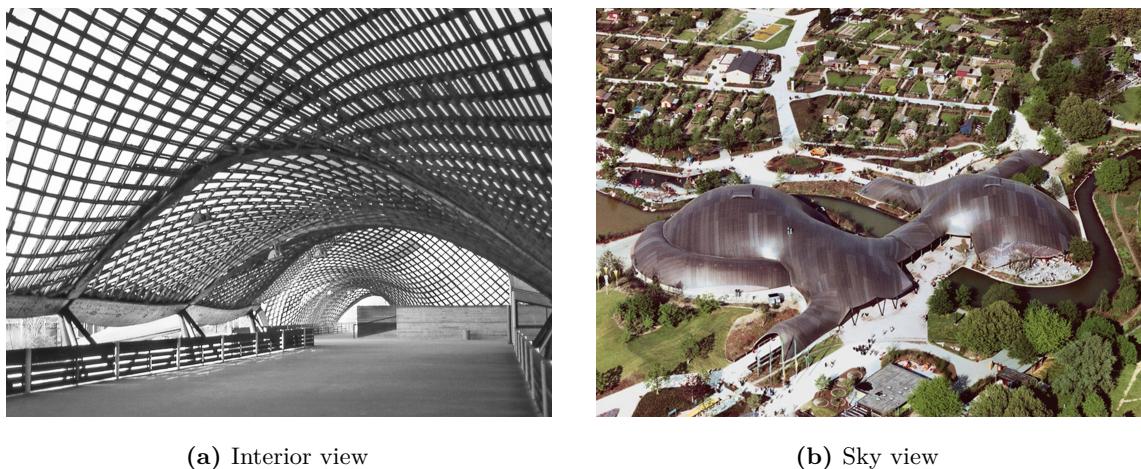

Figure 1.5 – Timber gridshell built in 1975 in Mannheim, Germany.

two grids, one sliding on top of the other one, were connected together to form a single grid with much higher ladder profiles (from 50 mm to 150 mm), increasing their bending stiffness by 26 (see fig. 1.5a).

Because the in-plane stiffness of the grid also plays a major role in the resistance to buckling, this question was considered with care. The bracing of the grid was first achieved by preventing the nodes to turn once the grid was erected. This was done by creating some friction in the nodes when tightening the bolts linking the laths, after the grid was erected. Additional bracing cables were put in the grid.

Finally, the project of Mannheim was a key project in the development of modern lightweight structures. Great engineers were born in touch with Frei Otto, following its footsteps or collaborating with him. This heritage has irrigated for several decades the engineering of lightweight structures in Europe and gave birth, directly or indirectly, to several studios among which we can cite *Buro Happold*, *Schlaich Bergermann & Partner* and *RFR*.

1.2.3 The dry period : 25 years from Mannheim to Hannover

Although the experience of Mannheim proved the feasibility and the potential of gridshell structures for large-scale projects, it also revealed that these projects were subject to an incredible complexity in terms of structural design, geometry, modeling, testing, team work, construction methods, ... At that time, very few people could pretend to master all the knowledge and techniques required to design and build timber gridshells and developed in the bosom of the *Institute for Lightweight Structures* in Stuttgart.

This project was obviously well ahead of its time and the engineering cost to design such structures was probably prohibitive considering the tools available at that time. This certainly explains why no elastic gridshells were built during the 25 following years, despite

the optimism of the pioneers of the Multihalle.⁸

Note that around 1975 small workshop and experiments lead to the construction of several but small elastic gridshells, as reported in [11]. A non-exhaustive but quite extensive list of known executed gridshell projects is presented in fig. 1.1. The dry period is clearly visible.

1.2.4 The signs of a renewal : Dorset and Doncaster

It is only 20 years later that gridshells started to reappear, in the late 90's mainly in the United Kingdom, and for projects that had interest in environmental problematics.

Westminster Lodge, Dorset, England, 1995

In 1995, a small student residence named *Westminster Lodge* was built in Dorset, England. This dwelling was part of a larger project – Hooke Park – aiming at investigating how the local forest resources, in particular immature roundwood thinnings, could be better utilized. The project was lead by ABK, Frei Otto, Buro Happold and Cullinan Studio. Unlike Mannheim, the timber shell was bent and weaved rod by rod on a scaffold platform. But the structural system exhibited a double-layer gridshell pattern very similar to the one employed for the Multihalle (see fig. 1.6a). The rods were made out of splice-jointed roundwood to form long-length poles of diameter 200 mm. The development of this jointing technique, which could be produced directly in the forest, was part of the project's investigations [12]. The grid was braced by a layer of diagonal boards nailed to the roundwoods. The structure was finally cladded with a planted turf roof (see fig. 1.6b).

Earth Center, Doncaster, England, 1998

At the same time, a project of a similar spirit arose for the *Earth Center* in Doncaster, England.⁹ The project planning started in 1994 and a series of small timber gridshells were designed by Buro Happold and then built in 1998. The landscape structures were single-layer timber gridshells made with oak laths. Once erected with a crane, the grids were braced with crossing diagonal stainless steel cables (see fig. 1.7a). Openings were possibly reinforced with curved timber frames (see fig. 1.7b).

These projects definitely trailed the technique in England and initiated the renewal period (see §1.2.5). Although they remained small-scale projects for which modeling was achieved through physical models, they trained and restored partially the operational ability of Buro Happold to design timber gridshells as pointed by Harris et al. [34].

⁸“For many years after its completion, Happold promoted the benefit of the timber gridshell as a construction technique and stated that he could not understand why it had not been adopted more widely. He perceived the benefits to be in the efficiency of the construction method to enable doubly curved (shell) structures to be constructed quickly and cost effectively.” [34].

⁹“The Earth Centre Forest Garden was intended to demonstrate how managed woodland could supply the vast majority of all natural resources needed for human survival.”

1.2. Elastic gridshells : a thorough project review

Figure 1.6 – Roundwood gridshell built in 1995 in Dorset, England.

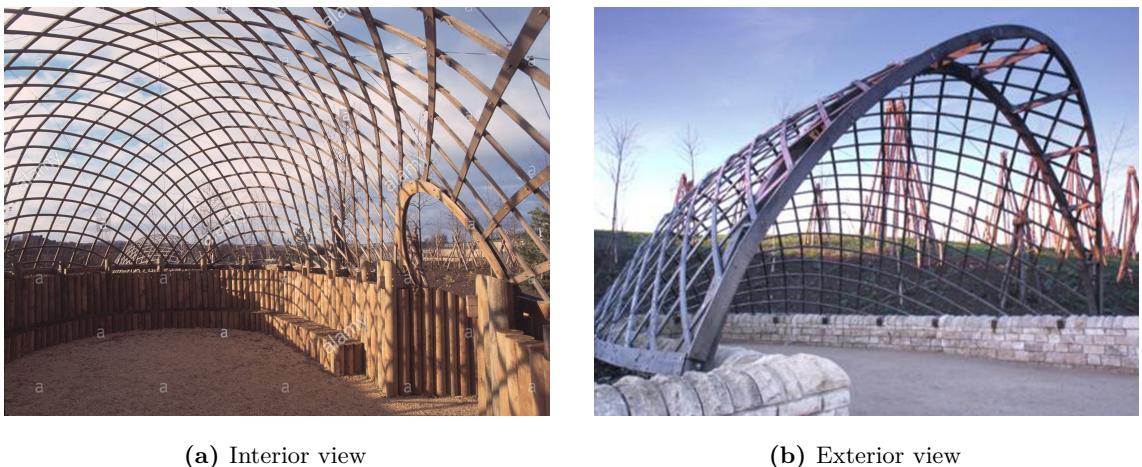

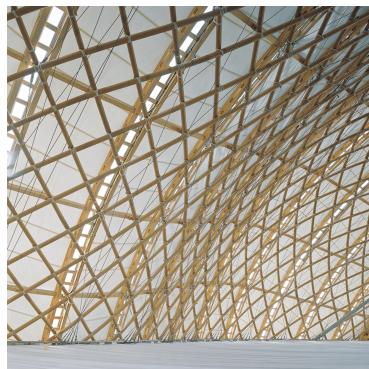

Figure 1.7 – Timber gridshells built in 1998 in Doncaster, England

1.2.5 The renewal : Hannover, Downland and Savill

What was missing for elastic gridshells to re-emerge after the major experiment of Mannheim was probably the development of modern numeric tools to ease and speed up the design process.¹⁰ Amongst those tools we should identify two main categories : geometry processing softwares and structural analysis softwares. Recall that in the 70's, geometry processing was done through physical models and photographic measurements [11, pp. 130-135] while structural analysis was conducted through a compound of physical model testing with scaling techniques [10, pp. 130-135], hand calculations and the very first numerical

¹⁰"The key to the modern use of timber gridshells is the development of computer methods in modelling complex three-dimensional shell structures. For the Mannheim structure, the primary method of form finding was the use of physical models. The Earth Centre structures were small and easily modelled using wire mesh, but when Buro Happold were commissioned to design the Japanese Pavilion for Expo 2000 in Hannover (Architect Shigeru Ban), it was apparent that much more sophisticated computer form finding and analysis would be necessary." [34]

(a) Interior view

(b) Sky view

Figure 1.8 – Carboard gridshell built in 2000 in Hannover, Germany.

formfinding calculations [11, pp. 184-193] and finite element calculations [11, pp. 210-217].

In the late 90's, the rise in importance of computer methods offered new possibilities.

Japan Pavilion, Hannover, Germany, 2000

In 1997, architecte Shigeru Ban began to collaborate with Frei Otto and Buro Happold to design the *Japan Pavilion* for *Expo 2000* in Hannover, Germany [51]. This pavilion was a large-scale corrugated gridshell made out of cardboard tubes, about 75 meters long and 25 meters wide. Corrugations bring curvature, and therefore enhance the strength of the shell. The tubes were tied together with a fabric tape, a very low-tech joint (see fig. 1.8a). The structure was covered with a paper membrane specially developed for the project to meet the requirements of the german fire regulations (see fig. 1.8b). For the occasion, a new erection method was set up in which the grid was laid out not at the ground level but at a higher level on a hydraulic scaffold platform. From there, the grid was pushed up into position using the platform's jacks. It was found late that the cardboard tubes were subject to a high level of creep. This required the introduction of new timber arches to reinforce the gridshell and to enlarge the existing timber rafters intended to brace the grid and support the paper membrane (see fig. 1.8a).

Weald and Downland, Singelton, England, 2002

The design of the *Downland* gridshell began right after the completion of the Westminster Lodge (see §1.2.4) where architects from E. Cullinan Studio became acquainted with the engineers from Buro Happold. At Downland, the project team truly revived the technique of large-scale timber gridshells while bringing lots of improvements to the system. The building opened to the public in 2002. Its corrugated shape recalls the one of the Japan Pavilion from which it was inspired (see fig. 1.9b).

The building is 50 meters long and 12.5 to 16 meters wide, covering an area of about 675 m^2

1.2. Elastic gridshells : a thorough project review

for a height varying from 7 to 9.5 meters [33]. The structure is a double-layer gridshell made of rectangular oak laths of cross-section 50 mm x 35 mm (see fig. 1.9a). To produce high grade timber elements, the continuous laths were re-formed from small carefully selected wood pieces, finger-jointed every 60 cm in 6.0 m length pieces. These pieces of lath were then scarf-jointed on site every 6 m to obtain the desired length, up to 50 m.

(a) Interior view

(b) Exterior view

Figure 1.9 – Timber gridshell built in 2003 in Downland, England.

The grid pitch is 1.0 m except in weaker areas where it is 0.5 m. There, the grid is twice denser to achieve the required buckling resistance [34]. Rib-lath bracing was preferred to steel cable bracing as ribs were deemed to offer a more convenient support for the cladding elements and to reduce the complexity of the connection. A new connection system was developed to avoid the cost of drilling thousands of slotted holes that would, in addition, reduce the cross-section area, while maintaining the required scissor behavior for the deformation of the timber lattice.¹¹

The flat lattice was laid out on a scaffold platform. Unlike the Japan Pavilion, the lattice was progressively lowered down into position. This stage took 6 weeks. Once deformed, the shear blocks were introduced in the grid and bracing rib-laths were installed, giving its full strength to the shell. Finally the gridshell was cladded with a mix of polycarbonate plates (to let the light in) and timber boards on top of insulation panels and a rain screen.

It is worth mentioning that for the first time the form was not found by inverting some sort of hanging chain model that would produce a pure funicular shape where only compression occurred. Instead, the shape was the result of a numerical computation that took into account the bending behavior of the laths.¹² Harris et al. [34] argued that computer models enabled some interactivity in the formfinding process that would not be possible with physical models, leading to a better synergy between architectural and structural requirements. They also argued that physical models contributed invaluable to

¹¹This detail was patented by the design team and the client.

¹²This software was developed by Chris Williams of the University of Bath.

the development of a creative and efficient design throughout the project.

Lothian Gridshell, Pishwanton, Scotland, 2002

This project deserves some attention because the developed approach was completely different from the projects exposed until now : “Previous projects have portrayed the method as a highly technical use of a low tech resource. This, however, need not be the case as we see with this project [...]” [48]. The structure was the result of “[...] an unusual collaboration between sole practitioner Christopher Day, engineer David Tasker, a crowd of local volunteers and (more unusually) the philosophies of Rudolf Steiner and Johann Wolfgang Goethe” [6].¹³ The single-layer gridshell was made out of local larch. Once erected

(a) Interior view

(b) Exterior view

Figure 1.10 – Timber gridshell built in 2002 in Pishwanton, England.

by hands, the dome-like shape covered about 80m^2 and spanned 10 meters. The grid was braced with timber boards (see fig. 1.10a) and covered with a planted turf roof (see fig. 1.10b). Some calculations were made but in the end, it had to carry load testing to prove its safety and gain its regulation approval.¹⁴

Woodland Centre, Filmwell, England, 2003

The gridshell of the Woodland Center was built 7 years after the project had started (fig. 1.11a).¹⁵ The building was designed by architect Feilden Clegg and engineers from Atelier One. It was part of a larger research and development project that aimed at

¹³From the online paper “The other gridshell” : <http://www.bdonline.co.uk/the-other-gridshell/1020435.article>

¹⁴“There were a lot of calculations but no computer-generated models to show they all added up. In fact, the form was previously established with scale models. When it came to gaining Building Regulations approval, the team needed to prove that the building would be strong enough. So Tasker arranged for the unfinished structure to be loaded with about 18 tonnes of sand from a local quarry – equivalent to the maximum predicted snow load, plus a safety factor.” [6]

¹⁵More to be found at : [Growing and making Flimwell’s chestnut gridshell](#).

developing chestnut – a low grad wood – as a construction material.¹⁶

Figure 1.11 – Timber gridshell built in 2003 in Filmwell, England.

The building, still existing, is composed of 5 barrel vaults spanning 12 meters and about 5 meters wide (see fig. 1.11b). It covers about 300 m^2 [47]. Each vault module is a transportable unit composed of two curved arches. A single layer gridshell was then applied to this primary frame and braced with chestnut panels. The grid was made of laths with $75 \text{ mm} \times 25 \text{ mm}$ rectangular cross-section, assembled with simple bolts. On top of that, insulation materials and a membrane as rainscreen [29].

Savill Garden, Englefield Green, England, 2006

This project saw the light of day thanks to the reputation of the gridshell built in Downland. Again, Buro Happold did the structural design while Green Oak Carpentry realized it. But this time, the architect was Glenn Howells.

The *Savill* gridshell is 90 meters long and 25 meters wide. It covers an area of about 2000 m^2 , and is therefore almost three times larger than the gridshell in Downland. Once again, the corrugated shape was defined by a parametric equation ($z = f(x, y)$) to enable interactivity between architects and engineers during the formfinding process (see fig. 1.12b). Chris Williams was responsible for this job.

In Savill, the forming strategy was quite different than those employed in Mannheim, Hannover or Downland [32]. Firstly, a single layer gridshell – constituted by the bottom two laths jointed with simple bolts – was deformed into the target shape. Secondly, the shear blocks were screwed on these laths. Thirdly, the upper two laths were positioned and screwed on top of the shear blocks to re-form a double-layer gridshell. Finally, the grid was then braced with two alternate layers of plywood boards, 12 mm thick each. Bracing the grid with continuous panels instead of cables or diagonal elements was a major architectural

¹⁶This project was conducted by the Building Research Establishment.

(a) Interior view

(b) Exterior view

Figure 1.12 – Timber gridshell built in 2006 in Savill, England.

choice (see [fig. 1.12a](#)). More over, it gave a well-defined surface for the cladding composed of 160 mm of insulation, covered by a waterproof aluminium layer made with standing-seam profiles supporting the oak boards [\[63\]](#).

Another consequence of this forming process was the drastic simplification of the connexion. The system developed for Downland was of no utility in that case and only simple bolts and screws were required. In this project, the pitch of this grid is 1.0 m. The 20 kms of laths are made from larch and have a 80 mm x 50 mm rectangular cross-section. They are spaced from 100 mm to 150 mm by the shear blocks.

Of course, the steel perimeter is a major component of the project but is not in the scope of this thesis. For further details the reader is invited to refer to Harris et al. [\[32\]](#) and Trada [\[63\]](#).

Chiddington Castle Orangery, Kent, England, 2007

The gridshell covering the orangery of Chiddington Castle is a very small one. Built in 2007, it is 12 meters long, 5 meters wide and covers about 50 m² (see [fig. 1.13b](#)). The structural system is derived from the one employed in Downland and is, once again, developed by Buro Happold and the Green Oak Caprentery. But this time the architecte is Peter Hulbert.

However this project embed some interesting innovations. Indeed, this time the gridshell is braced with a bidirectional cable network. Twin cables are employed to facilitate clamping on the node connection, which has been adapted from the previous version developed in Downland. This connection is now equipped with an additional threaded hole which can receive the clamping supports for the glazing (see [fig. 1.13a](#)). The timber shell is then glazed with triangular panels. Note that the quadrangles of the mesh are not planar any more in the deformed configuration and therefore triangulation of the panels is mandatory.

Figure 1.13 – Timber gridshell built in 2007 in Kent, England.

1.2.6 Gridshell in composite materials : a new perspective

Since 2002, the laboratory [Navier](#) at the Ecole des Ponts ParisTech develops a research program on elastic gridshells that is still ongoing. It focuses on both the use of new materials such as composite materials and the development of modern computer design methods for the generation of complex shapes, the formfinding and the structural analysis.

Douthe et al. [22] proved that composite materials in glass fiber reinforced polymers (GFRP) are very suitable for this type of structures where both flexibility and strength of the profiles are required. On the level of mechanical behavior GFRP surpass wood. They are easy and cheap to produce in long length when they are manufactured by pultrusion, thus avoiding complex jointing issues.¹⁷.

The first gridshells in composite material, Champs-sur-Marne, France, 2007

These developments have been validated by the construction of two prototypes in 2007 (see [fig. 1.21b](#)) and in 2008 (see [1.14b](#)) [21]. These structures were left outside for about 7 years. They covered about 150 m² each, spanning around 13 meters. The structures were single-layer gridshells made with pultruded GFRP tubes ($\varnothing 41.7 \text{ mm} \times 3.5 \text{ mm}$) assembled with a standard scaffold swivel connector. The grid were braced with a third layer of tubes and covered with a PVC coated fabric membrane providing full waterproofness.

Here, the performance of composite materials is of real benefit. A single-layer gridshell is enough for this span. The hollow circular cross-section make optimal use of the material. Tubes are provided in 12 meters length and therefore no joints are required for this span. In the end, all these benefits make the constructive system a lot more lighter, simpler and efficient than what a timber gridshell would offer.

¹⁷Video explaining the pultrusion process : https://www.youtube.com/watch?v=4MoHNZB5b_Y

(a) First prototype (2007)

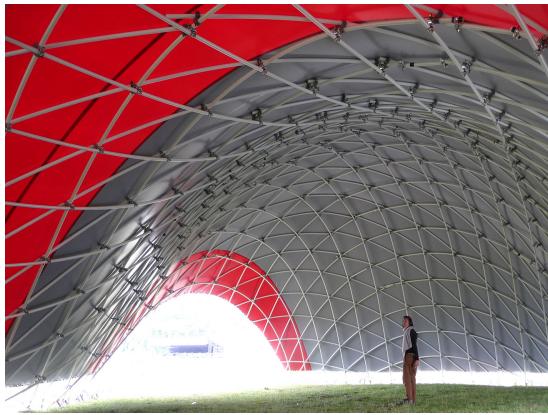

(b) Second prototype (2008)

Figure 1.14 – GFRP gridshell built in 2007 in Noisy-Champs, France.

Solidays, Champs sur Marne, France, 2011

In 2011, [Navier](#) used its knowledge to design with a team of students a temporary pavilion for a music festival in Paris, France (see [fig. 1.15b](#)).¹⁸ Although the constructive system was similar to the one employed for the two prototypes, the size and the span were more than twice larger [5]. In addition, it was the first gridshell in composite material that hosted some public and therefore had to comply with strict building regulations.

(a) First prototype (2007)

(b) Second prototype (2008)

Figure 1.15 – GFRP gridshell built in 2011 in Paris, France.

To our knowledge, it is also the first gridshell that was designed using the compass method [11], thus providing an inverse method to design the structure directly from the shape given by the architect. The single-layer gridshell covered about 280 m² and was erected by

¹⁸Photos and videos of the construction process are available at : <http://thinkshell.fr/gridshell-solidays-2011/>

two mobile cranes (see fig. 1.15a).

Ephemeral Cathedral, Crêteil, France, 2013

The *Ephemeral Cathedral* of Crêteil is the last achievement of this kind [25].¹⁹ It was designed by T/E/S/S with the assistance of Navier. This time the structure is a real building meant to last a decade and is still in activity since its construction in 2013. A complete review of this project is given in the next chapter of this thesis (see ??).

(a) Interior view

(b) Exterior view

Figure 1.16 – GFRP gridshell built in 2013 in Crêteil, France.

The single-layer gridshell covers about 350 m² and spans 17 meters (see fig. 1.16a). It is covered by a PVC coated fabric membrane (see fig. 1.16b). It was erected by two mobile cranes.

1.2.7 Flourishing timber gridshell pavilions

Since 2010, about 20 timber gridshell pavilions were built around the world, mainly during workshops. Here, we do not review all this pavilions in detail because they are quite similar although each one has its specificities.

The impetus given by gridshell.it

Around 2010, a research group gathering architectural and engineering skills appeared under the name [gridshell.it](#) in Italy. Inspired by the work of Frei Otto, they revisited the structural system developed at Mannheim and adapted it to a range of small-scale timber pavilions.

¹⁹Photos and videos of the construction process are available at : <http://thinkshell.fr/gridshell-cathedral-2013/>

(a) Lecce, 2010

(b) Toledo 2.0, 2014

Figure 1.17 – Timber gridshells built by gridshell.it in Italy.

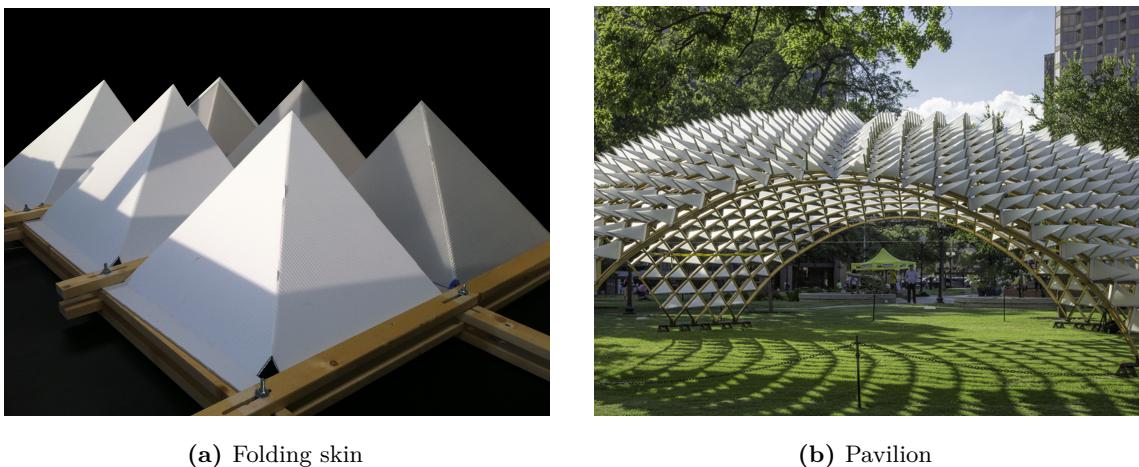

These pavilions have in common to be double-layer timber gridshells. The structural system is always composed of laths with rectangular cross-section. The laths come in short length from the sawmill (about 3 to 4 meters). They do not try to re-form long-length laths with complex jointing techniques. Instead, they use a simple splice system. Although it is not very pleasant visually, it is efficient enough for this kind of project. As the laths are short, this detail is repeated frequently in the grid. However the splice system enable a higher level of prefabrication of the grid. Thus, small modules of the size of the laths can be preassembled and connected with the splice system to re-form the full grid. This gridshells are braced either with cables or with individual diagonal elements in each cell.

These structures were never meant to provide full waterproofness although some were an occasion to experiment different types of cladding with boards (Lecce 2010, Toledo 2012, Milano 2013,) or with textile membranes (Lecce 2009).

One of their first pavilion was built in 2010 in Lecce, Italy (see fig. 1.17a). Their most known project is probably the Toledo pavilion built in 2012 in Naples, Italy. A new pavilion called Toledo 2.0 was built in 2014 in Naples, Italy (see fig. 1.17b). Although it seems that their initial approach focused more on the architectural aspects and the construction process, they rapidly tried to develop dedicated computer design methods [16] and did serious wood testing [17].

Other similar timber pavilions

The ideas of the gridshell.it group spread rapidly and similar projects were achieved outside of Italy. Amongst them, we can point out the ZA pavilion built in 2013 in Cluj, Romania [55] ; the F² pavilion built in 2014 in San Antonio, USA, with an interesting folding skin (see figures 1.18a and 1.18b) ; and the pavilion built in 2016 in Trondheim, Norway, which is made of very short length laths spliced every two cells [30].

(a) Folding skin

Figure 1.18 – Timber gridshell built in 2013 in San Antonio, USA.

Specific inputs from the laboratory Navier

In that vein, [Navier](#) and engineers from [Terrell](#) helped two students from the [ENSA Grenoble](#) and [ENSA Toulouse](#) to design a modular pavilion system for their final year project (2016). These pavilions were designed similarly to the pavilions of [gridshell.it](#) but improvements were made. Firstly, a new cable bracing system was developed. It was embedded in the grid and tensioned with spacer plates once the grid was erected (see [fig. 1.19a](#)). This system proved its efficiency on site compared to bracing with diagonal elements. Secondly, the grid was designed and fabricated so it could be dismantled and reassembled in a different shape. And indeed, a first pavilion was erected in Toulouse the 3rd of June, dismantled, reconfigured, and re-erected in Montpellier the 15th of June. The pavilions shared the same standard grid modules (2.40 m x 2.40 m). Dedicated modules were used to adapt the change in shape.²⁰

1.2.8 Latest experiments

In 2016, a one-week workshop called [Building Freeform 2016](#) was held at the Ecole des Ponts ParisTech, France. The brief was to explore some innovative methods, including the generation of forms authorizing the coverage by flat panels as well as the automation of some production tasks with the use of a robot arm (see [fig. 1.20a](#)). The draft studies were conducted upstream of the week, so that students can focus on design issues, implementation and practical achievement.²¹

²⁰For these projects, I did the gridfinding with the compass method, the formfinding with my own dynamic relaxation software, wood testing and specification, grid system detailing (nodes, cross-sections, grid pitch, bracing, slotted holes, shear blocks, ...) and provided a valuable assistance all along the project.

²¹The co-development of this week was part of my research work. In particular, I provided the formfinding and structural analysis tools and developed the upstream software to generate the fabrication informations required by the milling station. This software was largely parametric so students can truly implement their own design. I was also involved in the planning of the week.

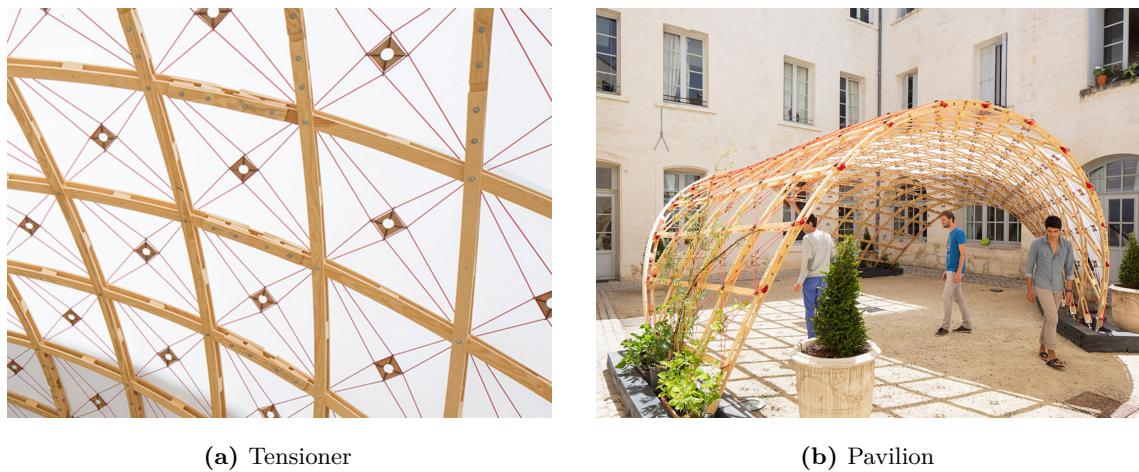

Figure 1.19 – Timber gridshell built in 2016 in Montpellier, France.

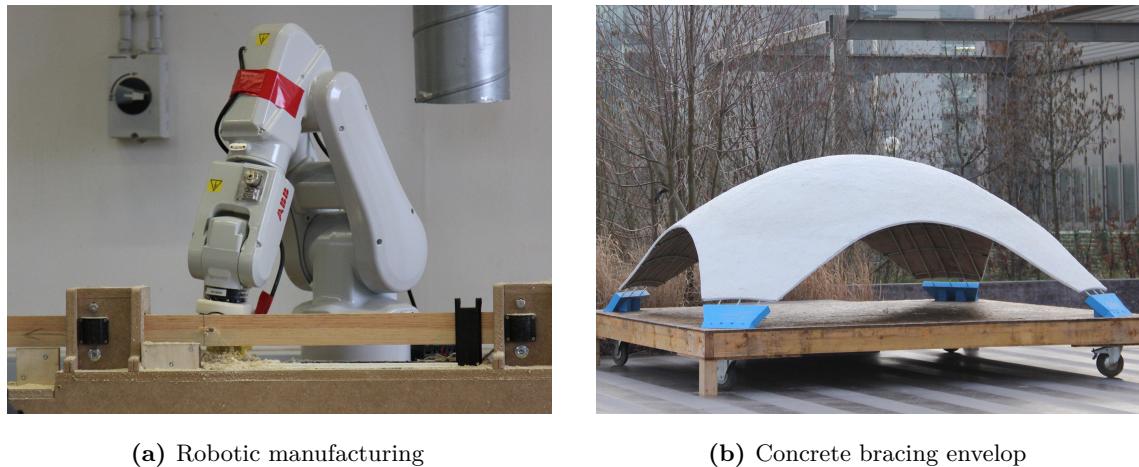

Figure 1.20 – Recent experiments built in 2016 in Champs-sur-Marne, France.

The second experiment is a hybrid structure (see fig. 1.20b). It is part of our reflexion at [Navier](#) on how to brace and clad gridshells. Indeed, the bracing of the grid in its final form remains a time consuming step with a lot of manual work. The lack of alternatives to membrane covering is also an important limitation to the development of such technology. The proposed experiment tries to tackle both issues through a novel concept of a hybrid structural skin made of an elastic gridshell braced with a concrete envelope. The idea is to use the gridshell as a formwork for the concrete and to guarantee a mechanical connection between the thin concrete skin and the main grid, so that the concrete ensures the bracing of the grid and that the thickness of the concrete is reduced to a minimum. To demonstrate the feasibility and interest of this structural concept, a 10 m² prototype was built at the Ecole des Ponts ParisTech, France (see fig. 1.20b). The main aspects of the design and of the realization of the prototype are presented by Cuvilliers et al. 2017 [15]

1.3 Research works in the field of elastic gridshells : a review

In this section we depict the research works that are related to elastic gridshells. Several topics have been identified to organize the review.

1.3.1 Mechanics

1.3.2 Geometry

In *IL10 Grid Shells*, Burkhardt et al. 1974 [11] study the uniform mesh net with square meshes. They propose a classification for suspended nets (pp. 68-69) and give an inventory of common problems such as overlapping and singularities. They explain how to build valuable physical models for hanging nets (pp. 50-55) and how to measure them with either close-range stereo-photogrammetry, a simple measuring table or the parallel light measurement technique (pp. 130-134). Finally, they propose a geometric method to find square meshes from a given curved shape and called the *compass method* (pp. 140-141).

Bouhaya et al. 2009 [9] propose an alternative to the compass method for finding gridshell meshes on an imposed surface. This method consists in numerically dropping a grid onto a fixed shape. The simulation is achieved with a dynamic explicit finite element solver. Therefore, the proposed method can take into account the real mechanics of the grid, which is not possible with the compass method.

Bouhaya et al. 2014 [8] implement the compass method in a geometry software. For a fixed mesh size and starting point they parametrically generate a large number of discrete guidelines on the surface. The generation is controlled by a vector of angles controlling the expansion of a guideline on the surface. The method is then coupled with a genetic algorithm to find meshes where curvature is minimized for the elements.

Lafuente Hernandez et al. 2012 [42] propose a variational approach to find grids that minimize the curvature of the elements. This is done by introducing penalty energies. Consequently, the mesh is allowed to move away from the imposed shape and the bars are allowed to dilate from their initial length.

du Peloux et al. 2011 [24] implement the compass method in Rhino and Grasshopper. They use it to design two large-scale gridshells in composite materials in 2011 [5] and 2003 [25].

Lefevre et al. 2015 [43] propose an extended compass method that takes into account the eccentricity that exists between the layers of elements. This gap is generally due to the connection system.

Masson and Monasse 2017 [50] prove the existence of a global smooth Chebyshev net on complete, simply connected surfaces when the total absolute curvature is bounded by 2π . His thesis tries to understand when a given surface is meshable by a gridshell net and how to mesh larger portions of a given surface by connecting several pieces of Chebyshev net and dealing with singularities.

1.4 Gridshell structure : definition and classification

1.4.1 Historic overview

1.4.2 Rigid gridshell

1.5 Elastic gridshells : revisiting Mannheim

1.6 Elastic gridshells : the benefits of composite materials

Glass fiber reinforced polymer (GFRP) tubes are at the heart of the presented technology. They can favorably replace wood where both resistance and bending ability of the material is sought [Douthe2010].

The tubes are made by pultrusion, “a continuous molding process whereby reinforcing fibers are saturated with a liquid polymer resin and then carefully formed and pulled through a heated die to form a part. Pultrusion results in straight constant cross section parts of virtually any shippable length”.²⁴ This process is very economic and its standardization guarantees very stable material and mechanical properties. It frees designers from the problem of joining wood pieces with finger joints to obtain long and continuous members and of wood durability.

1.6.1 Recent developments

The Faraday Pavilion : [56] The Pishwanton / lothian : [Pishwanton2003] The laboratory Navier tested various numerical methods to generate such grids [9] Masson : [50].

1.6.2 Gridshell in composite material

The benefits of GFRP gridshells have been covered previously. We just recall the main aspects.

The gridshells built in composite material, being at the heart of this paper, are consistent with the framework defined previously, that is to say :

Glass fiber reinforced polymer (GFRP) tubes are at the heart of the presented technology. They can favorably replace wood where both resistance and bending ability of the material is sought [Douthe2010].

The tubes are made by pultrusion, “a continuous molding process whereby reinforcing fibers

are saturated with a liquid polymer resin and then carefully formed and pulled through a heated die to form a part. Pultrusion results in straight constant cross section parts of virtually any shippable length”²⁵ This process is very economic and its standardization guarantees very stable material and mechanical properties. It frees designers from the problem of joining wood pieces with finger joints to obtain long and continuous members and of wood durability.

Structural Typology

Their mechanical behaviour is very similar to the one of real shells even if the material is discrete and located in a grid more or less open. In spite of that, gridshells benefit from the same advantages as the ones showed by an eggshell : they can cross large span using a low amount of material. Their stiffness is mainly linked to their double-curved shape.

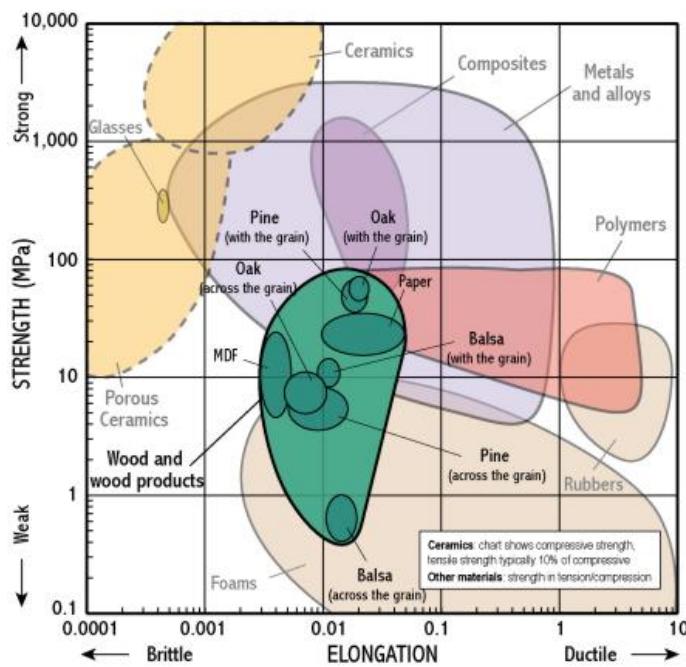

Material Flexibility for Structural Rigidity

In this field of application, composite materials like glass fibre reinforced polymer (GFRP) could favourably replace wood, where both resistance and bending ability of the material is sought [Douthet2010]. The stiffness of the structure does not derive from the intrinsic material rigidity but principally from its geometric curvature. Ideally, the composite profiles are produced by pultrusion, an economic continuous moulded process. The standardization of the process guarantees very stable material and mechanical properties. It frees designers from the painful problematic of wood joining and wood durability. The characterization of this material is presented further in the paper.

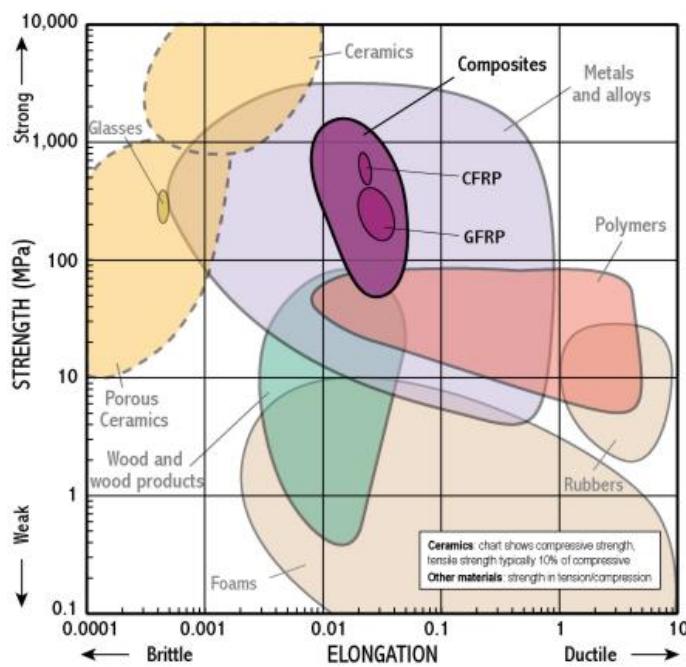

Erection Process

Usually, the grid morphology is not trivial and leads to design numerous costly and complex joints. To overcome this issue, an original and innovative erection process was developed that takes advantage of the flexibility inherent to slender elements. A regular planar grid made of long continuous linear members is built on the ground (Figure 1.23a). The elements are pinned together so the grid has no in-plane shear stiffness and can accommodate large-scale deformations during erection. Then, the grid is bent elastically to its final shape (Figure 1.22). Finally, the grid is frozen in the desired shape with a third layer of bracing members (Figure 1.23b) and the structure becomes a shell.
